In re Patent Application of:	
Bob BUCHANAN et al.	
Application No.: 10/067,484	Group Art Unit: 1644
Filed: February 4, 2002	Examiner: P. J. Nolan
For: Ragweed Allergens	

**Declaration of Bob B. Buchanan Pursuant to 37 C.F.R § 1.132**

Commissioner for Patents  
P.O. Box 1450  
Alexandria, VA 22313-1450

Dear Sir:

I, Bob B. Buchanan, declare as follows:

1. I am an inventor named in the above-referenced patent application.
2. I am a Professor of Plant and Microbial Biology at the University of California, Berkeley. I have reviewed the del Val et al. abstract (Journal of Allergy and Clinical Immunology (2001) 107 (2): S318) cited by the Examiner, and on which I am the senior author.
3. Joshua H. Wong is listed as a co-author on the del Val et al. abstract.
4. Joshua H. Wong was a research associate in my laboratory and the work he performed on the extractions and purification was done under either the supervision and direction of either me or Gregorio del Val. Joshua H. Wong did not make any independent contribution to the work described in the article.
5. Either Gregorio del Val or I chose the procedures and criteria to be followed for conducting the relevant studies. Joshua H. Wong assisted with certain of the extractions and purification steps. We instructed Joshua H. Wong to follow these procedures, and he reported the results of the studies to us.
6. The nature of the work performed by Joshua H. Wong is summarized as

follows. Joshua H. Wong performed the following empirical studies under my direction and supervision.

- 1 Helped prepare pollen extracts.
- 2 Assisted with certain steps of purification of the allergen protein.

8. I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code, and that such willful false statements may jeopardize the validity of the application, any patent issuing thereon, or any patent to which this verified statement is directed.

# BRIEF SUMMARY

**FLOVENT® 44 mcg**  
(fluticasone propionate, 44 mcg)  
inhalation aerosol

**FLOVENT® 110 mcg**  
(fluticasone propionate, 110 mcg)  
inhalation aerosol

**FLOVENT® 220 mcg**  
(fluticasone propionate, 220 mcg)  
inhalation aerosol

For Oral Inhalation Only

The following is a brief summary only; see full prescribing information for complete product information.

**CONTRAINDICATIONS:** FLOVENT Inhalation Aerosol is contraindicated in the primary treatment of status asthmaticus or other acute episodes of asthma where intensive measures are required.

## WARNINGS:

Particular care is needed in patients who are transferred from systemically active corticosteroids to FLOVENT Inhalation Aerosol because deaths due to adrenal insufficiency have occurred in patients with asthma during and after transfer from systemic corticosteroids to less systemically available inhaled corticosteroids. After withdrawal from systemic corticosteroids, a number of months are required for recovery of hypothalamic-pituitary-adrenal (HPA) function.

Patients who have been previously treated on 20, 44, or more mg per day of prednisone for its equivalent may be most susceptible, particularly when their systemic corticosteroids have been almost completely discontinued. During this period of HPA suppression, patients may exhibit signs and symptoms of adrenal insufficiency when exposed to trauma, surgery, or infection (particularly respiratory) or other conditions associated with severe electrolyte loss. Although fluticasone propionate inhalation aerosol may prevent control of asthma symptoms during these episodes, in recommended doses it supplies less than normal physiological amounts of glucocorticoids systemically and does NOT provide the mineralocorticoid activity that is necessary for coping with these emergencies.

During periods of stress or a severe asthma attack, patients who have been withdrawn from systemic corticosteroids should be instructed to resume oral corticosteroids in large doses immediately and to contact their physicians for further instruction. These patients should also be instructed to carry a warning card indicating that they may need supplementary systemic corticosteroids during periods of stress or a severe asthma attack.

Patients requiring oral corticosteroids should be warned about the systemic corticosteroid use after transferring to fluticasone propionate inhalation aerosol. In a trial of 55 patients, prednisone reduction was successfully accomplished by reducing the prednisone dose by 2.5 mg on a weekly basis during transfer to inhaled fluticasone propionate. Successful reduction of prednisone dose was allowed only when lung function, symptoms, and as-needed short-acting oral beta<sub>2</sub>-agonist use were stable or improved before initiation of prednisone dose reduction. Lung function (forced expiratory volume in 1 second [FEV<sub>1</sub>] or morning peak expiratory flow rate [AMPEFR]) was assessed weekly, and asthma symptoms should be carefully monitored during withdrawal of oral corticosteroids. In addition to monitoring asthma symptoms, patients should be observed for signs and symptoms of adrenal insufficiency such as fatigue, lassitude, weakness, nausea and vomiting, and hypotension.

Transfer of patients from systemic corticosteroids to the 44 mcg fluticasone propionate inhalation aerosol may unmask conditions previously suppressed by the systemic corticosteroid therapy, e.g., diabetes, convulsions, myopia, and arthritis.

Persons who are on drugs that suppress the immune system are more susceptible to infections than healthy individuals. Chickenpox and measles, for example, can have a more serious or even fatal course in susceptible children or adults on corticosteroids. In such children or adults who have not had these diseases, particular care should be taken to avoid exposure. How the dose, route, and duration of corticosteroid administration affects the risk of developing a disseminated infection is not known. The continuation of the underlying disease and/or prior corticosteroid treatment to the risk is also not known. If exposed to chickenpox, prophylaxis with varicella zoster immune globulin (VZIG) may be indicated. If exposed to measles, prophylaxis with pooled intramuscular immunoglobulin (IG) may be indicated. See the respective package inserts for complete VZIG and IG prescribing information. If chickenpox develops, treatment with antiviral agents may be considered.

Fluticasone propionate inhalation aerosol is not to be regarded as a bronchodilator and is not indicated for rapid relief of bronchospasm.

As with other inhaled asthma medications, bronchospasm may occur with an immediate increase in wheezing after dosing. If bronchospasm occurs following dosing with FLOVENT Inhalation Aerosol, it should be treated immediately with a fast-acting inhaled bronchodilator. Treatment with FLOVENT Inhalation Aerosol should be discontinued and alternative therapy initiated.

Patients should be instructed to contact their physicians immediately when episodes of asthma that are not responsive to bronchodilators occur during the course of treatment with fluticasone propionate inhalation aerosol. During such episodes, patients may require therapy with oral corticosteroids.

## PRECAUTIONS:

**General:** During withdrawal from oral corticosteroids, some patients may experience symptoms of systemically active corticosteroid withdrawal, e.g., pain and/or muscular pain, lassitude, and depression, or even impairment of respiratory function.

Fluticasone propionate was often used in patients with asthma symptoms with less suppression of HPA function than therapeutically equivalent oral doses of prednisone. Since fluticasone propionate is absorbed into the circulation and can be systemically active at higher doses, the beneficial effects of fluticasone propionate inhalation aerosol in relieving HPA dysfunction may be expected only when recommended dosages are not exceeded and individual patients are followed to the extent effective use is maintained. A relationship between plasma levels of fluticasone propionate and inhibitory effects on stimulated cortisol production has been shown after 4 weeks of treatment with fluticasone propionate inhalation aerosol. Since individual sensitivity to effects on cortisol production exists, physicians should consider this information when prescribing fluticasone propionate inhalation aerosol.

Because of the possibility of systemic absorption of inhaled corticosteroids, patients treated with these drugs should be observed carefully for any evidence of systemic corticosteroid effects. Particular care should be taken in observing patients postoperatively or during periods of stress for evidence of inadequate adrenal response.

It is possible that systemic corticosteroid effects such as hypertension and adrenal suppression may appear in a small number of patients, particularly at higher doses. If such changes occur, fluticasone propionate inhalation aerosol should be reduced slowly, consistent with accepted procedures for reducing systemic corticosteroids and for management of asthma symptoms.

A reduction of growth velocity in children or teenagers may occur as a result of inadequate control of chronic diseases such as asthma or from use of corticosteroids for treatment. Physicians should follow the growth of adolescents taking corticosteroids by any route and weigh the benefits of corticosteroid therapy and asthma control against the possibility of growth suppression if an adolescent's growth appears slowed.

The long-term effects of fluticasone propionate in human subjects are not fully known. In particular, the effects resulting from chronic use of fluticasone propionate on developmental or immunologic processes in the mouth, pharynx, trachea, and lung are unknown. Some patients have received fluticasone propionate inhalation aerosol on a continuous basis for periods of 3 years or longer. In clinical studies with patients treated for nearly 2 years with inhaled fluticasone propionate, no apparent differences in the type or severity of adverse reactions were observed after long- versus short-term treatment.

Rare instances of glaucoma, increased intraocular pressure, and cataracts have been reported following the inhaled administration of corticosteroids, including fluticasone propionate.

In clinical studies with inhaled fluticasone propionate, the development of localized infections of the pharynx with *Candida albicans* has occurred. When such an infection develops it should be treated with appropriate local or systemic (i.e., oral antifungal) therapy while remaining on treatment with fluticasone propionate inhalation aerosol, but at times therapy with fluticasone propionate may need to be interrupted.

Inhaled corticosteroids should be used with caution, if at all, in patients with active or quiescent tuberculosis infection of the respiratory tract; untreated systemic (fungal, bacterial, viral, or parasitic) infections; or ocular herpes simplex.

**Eosinophilic Conditions:** In rare cases, patients on inhaled fluticasone propionate may present with systemic eosinophilic conditions, with some patients presenting with clinical features of vasculitis consistent with Churg-Strauss syndrome, a condition that is often treated with systemic corticosteroid therapy. These events usually, but not always, have been associated with the reduction and/or withdrawal of oral corticosteroid therapy following the introduction of fluticasone propionate. Cases of serious eosinophilic conditions have also been reported with other inhaled corticosteroids in clinical setting. Physicians should be alert to eosinophilia, vasculitic rash, worsening pulmonary symptoms, cardiac complications, and/or neuropathy presenting in their patients. A causal relationship between fluticasone propionate and these underlying conditions has not been established (see ADVERSE REACTIONS).

**Information for Patients:** Patients being treated with FLOVENT Inhalation Aerosol should receive the following information and instructions. This information is intended to aid them in the safe and effective use of this medication. It is not a substitute for all possible adverse or unwanted effects.

Patients should use FLOVENT Inhalation Aerosol at regular intervals as directed. Results of clinical trials indicated significant improvement may occur within the first day or two of treatment; however, the full benefits may not be achieved until treatment has been administered for 1 to 2 weeks or longer. The patient should not increase the amount of drug but should contact the physician if symptoms do not improve or if the condition worsens.

Patients should be warned to avoid exposure to chickenpox or measles and, if they are exposed, to consult their physicians without delay.

For the proper use of FLOVENT Inhalation Aerosol and to attain maximum improvement, the patient should read and follow carefully the accompanying patient's instructions for use.

**Contraception, Multigravida, Impairment of Fertility:** Fluticasone propionate demonstrated no tumorigenic potential in studies of oral doses up to 1000 mcg/kg (approximately 2 times the maximum human daily inhalation dose based on mcg/m<sup>2</sup>) for 78 weeks in the mouse or inhalation of up to 10 mcg/kg (approximately 1/4 the maximum human daily inhalation dose based on mcg/m<sup>2</sup>) for 104 weeks in the rat.

Fluticasone propionate did not induce gene mutation in prokaryotic or eukaryotic cells in vitro. No significant clastogenic effect was seen in cultured human lymphocytes in vitro or in the mouse micronucleus test when administered at high doses by the oral or subcutaneous routes.

Furthermore, the compound did not delay embryonic development in rats dosed subcutaneously with doses up to 50 mcg/kg approximately 1/4 the maximum human daily inhalation dose based on mcg/m<sup>2</sup> in males and females. However, prenatally weight was significantly reduced in rats.

**Reproduction, Reproductive Effects:** Pregnancy, Category C. Subcutaneous studies in the mouse and rat at 45 and 100 mcg/kg, respectively (approximately 1/10 and 1/2 the maximum human daily inhalation dose based on mcg/m<sup>2</sup>), respectively, revealed fetal toxicity characteristic of potent glucocorticoid compounds, including embryonic growth retardation, osteopenia, and reduced cranial ossification.

Other effects, including embryonic growth retardation, osteopenia, delayed palate, and reduced cranial ossification.

In the rabbit, fetal weight reduction and cleft palate were observed following subcutaneous doses of 4 mcg/kg (approximately 1/25 the maximum human daily inhalation dose based on mcg/m<sup>2</sup>). However, following oral administration of up to 300 mcg/kg (approximately 3 times the maximum human daily inhalation dose based on mcg/m<sup>2</sup>) of fluticasone propionate to the rabbit, there were no maternal effects nor increased incidence of external, visceral, or skeletal fetal defects. No fluticasone propionate was detected in the plasma in this study consistent with the established low bioavailability following oral administration (see CLINICAL PHARMACOLOGY section of full prescribing information).

Less than 0.003% of the administered dose crossed the placenta following oral administration of 100 mcg/kg in rats or 300 mcg/kg in rabbits approximately 1/2 and 1/3 times the maximum human daily inhalation dose based on mcg/m<sup>2</sup>, respectively.

There are no adequate and well-controlled studies in pregnant women. Fluticasone propionate should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Experience with oral glucocorticoids since their introduction in pharmacologic, as opposed to physiologic, doses suggests that rodents are more prone to teratogenic effects from glucocorticoids than humans. In addition, because there is a natural increase in glucocorticoid production during pregnancy, most women will require a lower exogenous glucocorticoid dose and many will not need glucocorticoid treatment during pregnancy. Nursing Mothers: It is not known whether fluticasone propionate is excreted in human breast milk. Subcutaneous administration of 10 mcg/kg intrateal drug to lactating rats (approximately 1/20 the maximum human daily inhalation dose based on mcg/m<sup>2</sup>) resulted in measurable radioactivity in both plasma and milk. Because glucocorticoids are excreted in human milk, caution should be exercised when fluticasone propionate inhalation aerosol is administered to a nursing woman.

**Pediatric Use:** One hundred thirty-seven (137) subjects between the ages of 12 and 16 years were treated with fluticasone propionate inhalation aerosol in the US pivotal clinical trials. The safety and effectiveness of FLOVENT Inhalation Aerosol in children below 12 years of age have not been established. Oral corticosteroids have been shown to cause a reduction in growth velocity in children and teenagers with extended use. If a child or teenager on any corticosteroid appears to have growth suppression, the possibility that they are particularly sensitive to this effect of corticosteroids should be considered (see PRECAUTIONS).

**Geriatric Use:** Five hundred seventy-four (574) patients 65 years of age or older have been treated with fluticasone propionate inhalation aerosol in US and non-US clinical trials. There were no differences in adverse reactions compared to those reported by younger patients.

**ADVERSE REACTIONS:** The following incidence of common adverse experiences is based upon 7 placebo-controlled US clinical trials in which 1243 patients (509 female and 734 male adolescents and adults previously treated with as-needed bronchodilators and/or inhaled corticosteroids) were treated with fluticasone propionate inhalation aerosol doses of 88 to 440 mcg twice daily for up to 12 weeks or placebo.

**Overall Adverse Experiences With >3% Incidence in Fluticasone Propionate in US Controlled Clinical Trials With MDI in Patients Previously Receiving Bronchodilators and/or Inhaled Corticosteroids**

Adverse Event	Placebo (n = 475) %	FLOVENT 88 mcg twice daily (n = 436) %	FLOVENT 220 mcg twice daily (n = 551) %	FLOVENT 440 mcg twice daily (n = 181) %
Ear, nose, and throat				
Pharyngitis	7	10	14	14
Nasal congestion	5	8	16	10
Sinusitis	1	3	6	5
Nasal discharge	3	5	4	4
Dysphonia	1	4	2	6
Allergic rhinitis	4	5	3	8
Oral candidiasis	1	2	3	5
Respiratory				
Upper respiratory infection	12	15	22	16
Influenza	2	3	8	3
Neurological				
Headache	14	17	22	17
Average duration of exposure (days)	44	66	64	59

The table above includes all events (whether considered drug-related or non-drug-related by the investigator) that occurred at a rate of over 3% in the combined fluticasone propionate inhalation aerosol groups and were more common than in the placebo group. In considering these data, differences in average duration of exposure should be taken into account.

These adverse reactions were mostly mild to moderate in severity, with 52% of patients discontinuing the studies because of adverse events. Rare cases of immediate and delayed hypersensitivity reactions, including urticaria and rash and other rare events of angioedema and bronchospasm, have been reported.

Systemic glucocorticoid side effects were not reported during controlled clinical trials with fluticasone propionate inhalation aerosol. If recommended doses are exceeded, however, or if individuals are particularly sensitive, symptoms of hypercorticism, e.g., Cushing's syndrome, could occur.

Other adverse events that occurred in these clinical trials using fluticasone propionate inhalation aerosol with an incidence of 1% to 3% and which occurred at a greater incidence than with placebo were:

Ear, Nose, and Throat: Pain in nasal sinuses; rhinitis;  
Eye: Irritation of the eyes;  
Gastrointestinal: Nausea and vomiting, diarrhea, dyspepsia and stomach disorders;  
Musculoskeletal: Fever;  
Mouth and Throat: Dental problem;  
Musculoskeletal: Pain in joint, sprain/strain, aches and pains, pain in limb;  
Neurological: Dizziness/headaches;  
Respiratory: Bronchitis, chest congestion;  
Skin: Dermatitis, rash, skin eruption;  
Urinary: Dysuria/dyschezia.

In a 16-week study in patients with asthma requiring oral corticosteroids, the effects of fluticasone propionate inhalation aerosol, 660 mcg twice daily (n = 32) and 880 mcg twice daily (n = 32), were compared with placebo. Adverse events (whether considered drug-related or non-drug-related by the investigator) reported by more than 3 patients in either fluticasone propionate group and which occurred at a greater incidence than placebo are shown below:

Ear, Nose, and Throat: Pharyngitis (9% and 25%), nasal congestion (19% and 22%), sinusitis (19% and 22%), nasal discharge (16% and 16%), dysphonia (19% and 9%), pain in nasal sinuses (13% and 9%), Candida-like oral lesions (16% and 9%), oropharyngeal candidiasis (25% and 19%).  
Respiratory: Upper respiratory infection (11% and 19%), influenza (9% and 13%).  
Other: Headache (28% and 34%), pain in joint (15% and 13%), nausea and vomiting (22% and 16%), muscular soreness (22% and 13%), rash/urticaria (22% and 28%), insomnia (3% and 13%).

**Observed During Clinical Practice:** In addition to adverse events reported from clinical trials, the following events have been identified during postapproval use of fluticasone propionate in clinical practice. Because they are reported voluntarily from a population of unknown size, estimates of frequency cannot be made. These events have been chosen for inclusion due to either their seriousness, frequency of reporting, causal connection to fluticasone propionate, or a combination of these factors.

Ear, Nose, and Throat: Throat soreness and irritation, hoarseness, laryngitis, aphonia.  
Endocrine and Metabolic: Cushingoid features, growth velocity reduction in children/adolescents, weight gain, hyperglycemia.  
Psychiatric: Restlessness, agitation, aggression, depression.  
Respiratory: Immediate bronchospasm, asthma exacerbation, dyspnea, wheeze, chest tightness, bronchospasm, cough.  
Skin: Pruritus, contusions, ecchymoses.

**Eosinophilic Conditions:** In rare cases, patients on inhaled fluticasone propionate may present with systemic eosinophilic conditions, with some patients presenting with clinical features of vasculitis consistent with Churg-Strauss syndrome, a condition that is often treated with systemic corticosteroid therapy. These events usually, but not always, have been associated with the reduction and/or withdrawal of oral corticosteroid therapy following the introduction of fluticasone propionate. Cases of serious eosinophilic conditions have also been reported with other inhaled corticosteroids in clinical setting. Physicians should be alert to eosinophilia, vasculitic rash, worsening pulmonary symptoms, cardiac complications, and/or neuropathy presenting in their patients. A causal relationship between fluticasone propionate and these underlying conditions has not been established (see PRECAUTIONS: Eosinophilic Conditions).

**OVERDOSE:** Chronic overdosage may result in signs/symptoms of hypercorticism (see PRECAUTIONS: Inhalation by healthy volunteers of a single dose of 1760 or 3520 mcg of fluticasone propionate inhalation aerosol was well tolerated. Fluticasone propionate given by inhalation aerosol at doses of 1320 mcg twice daily for 7 to 15 days to healthy human volunteers was also well tolerated. Repeat oral doses up to 80 mg daily for 10 days in healthy volunteers and repeat oral doses up to 20 mg daily for 42 days in patients were well tolerated. Adverse reactions were of mild or moderate severity, and incidences were similar in active and placebo treatment groups. The oral and subcutaneous median lethal doses in rats and mice were >1000 mcg/kg (>2000 times the maximum human daily inhalation dose based on mcg/m<sup>2</sup>).

**1036** A Comparison of Cutaneous, Conjunctival and Bronchial Reactivity to P Pratense

Gideon Luck, Graham Roberts, Cairiona Hurley. St Mary's Hospital, London, UK

**OBJECTIVE:** To determine whether there is a relationship between cutaneous, conjunctival and bronchial sensitivities to *Phleum pratense* (timothy grass) in individual children and teenagers with seasonal allergic asthma and rhinitis.

**METHODS:** 39 subjects (27 boys) aged 3 to 16 (average 11.9) years were assessed in this study. Specific IgE (Pharmacia Cap) to P pratense were assayed in all subjects. Skin prick testing was performed in 38 subjects with half-log, increasing concentrations of P pratense (ALK); the concentration giving a 3mm weal was determined by interpolation. Conjunctival testing was performed in all subjects using half-log, increasing concentrations of P pratense; the concentration giving a score of 5 on a standardised, validated scoring system recorded by one observer was determined by interpolation. Bronchial challenges with P pratense was performed in 25 subjects with half-log, increasing concentrations delivered by a Parijet nebuliser and lung function measured by Masterscreen spirometer (Jaeger); the PC20 was calculated. A comparison between the factors was made using correlation coefficients; the Bonferroni transformation was used to account for the multiple comparisons. Calculations were performed using Stata 6.

**RESULTS:** A significant correlation was found between specific IgE to P pratense and cutaneous sensitivity. However, no other significant relationships were found between specific IgE levels, cutaneous reactivity, conjunctival sensitivity or bronchial reactivity.

**CONCLUSIONS:** The data presented demonstrate that the sensitivities of different organs to P pratense are independent of each other. This agrees with the different patterns of clinical symptoms seen in children with grass pollen allergy.

Comparison between specific IgE and end-organ sensitivities

	Specific IgE	Cutaneous	Conjunctival	Bronchial
Specific IgE	-	-	-	-
Cutaneous	-0.568 (p=0.03)*	-	-	-
Conjunctival	-0.251 (p=1)	0.285 (p=0.40)	-	-
Bronchial	-0.403 (p=1)	0.208 (p=1)	0.138 (p=1)	-

\*Cutaneous sensitivity and specific IgE both logarithmically transformed. P values modified using the Bonferroni transformation to take into account the multiple comparisons.

**1037** Comparison of the Molecular and Immunological Properties of Natural and Recombinant Art v 1, the Major Allergen of *Artemisia Vulgaris* Pollen

Martin Himly\*, Renate Steiner\*, Ronald Van Ree\*, Christof Ebner\*, Fatima Ferreira\*. \*University of Salzburg, Salzburg, Austria §University of Vienna, Vienna, Austria ¶Central Laboratory of the Netherlands Blood Transfusion Service, Amsterdam, Netherlands

Pollen of mugwort (*Artemisia vulgaris*) represent one of the main causes for type I allergy in late summer and fall in Europe. Mugwort, a member of the Asteraceae or Compositae plant family, pollinates by wind and is widely distributed throughout the temperate climate regions of Central Europe. The major allergen of mugwort pollen has been determined by immunoblots with a large collection of sera from mugwort pollen-sensitized patients. This protein, which is recognized by 95 % of mugwort-allergic patients, was designated Art v 1. When subjected to SDS-PAGE it appears as a heterogeneous band in the MW range of 24 to 28 kDa. Recombinant Art v 1, in contrast, migrates at approximately 17 to 18 kDa, although the theoretical MW derived from the polypeptide chain is 10.8 kDa. Both natural and recombinant Art v 1 have been purified to homogeneity. In this study we report the molecular and immunological properties of purified recombinant Art v 1 in comparison to its natural counterpart. Natural Art v 1 was found to contain carbohydrate as demonstrated by positive PAS-staining. Mass measurements by Matrix-assisted laser desorption ionization-mass

spectrometry (MALDI-MS) were performed. By these means the molecular mass of purified recombinant Art v 1 was determined to be 10800, whereas in the case of purified natural Art v 1 two rather broad mass peaks with maxima at about 13400 and 15600 were detected. These differences in MW were assigned to the sugar content, which also turned out to protect the polypeptide chain from proteolytic digest. Binding experiments with plant lectins were performed in order to characterize the carbohydrate moieties. However, no common type of N-linked glycosylation could be detected. ELISA experiments with a panel of patients' sera revealed two distinct binding patterns of IgE antibodies: one class of sera reacted similarly with natural and recombinant Art v 1, whereas the other class showed extremely weak or no reactivity to recombinant in comparison to the natural allergen. In inhibition ELISA experiments, natural Art v 1 totally abolished the interaction of IgE with its recombinant counterpart, whereas recombinant Art v 1 gave only 50 % inhibition of IgE-binding to the natural allergen. Purified natural and recombinant Art v 1 were also subjected to periodate treatment and reduction/alkylation procedures. By subsequently performed immunoblotting and ELISA inhibition experiments with patients' sera more conclusions on the nature of the present IgE epitopes of natural and recombinant Art v 1 could be drawn. Taken together the results of this study show a high impact of glycosylation on the allergenicity of the major mugwort pollen allergen Art v 1.

**1038** A Major New Allergen From Ragweed Pollen

Greg Del Val\*, Joshua H Wong\*, Suzanne Teuber\*, Oscar L Frick\*, Bob B Buchanan\*. \*UC Berkeley, Berkeley, CA §UC Davis, Davis, CA ¶UC San Francisco, San Francisco, CA

Ragweed pollen has a lipid layer on the surface, which has been extracted and routinely discarded for more than 50 years in order to produce allergy test preparations. The symptoms in pollen allergy, that appear after a few minutes, are believed to be due to allergens located on the pollen surface, which includes the lipid layer. As it has been demonstrated with defatted ragweed pollen (Marsh DG et al JACI 1981, 67: 206-222), there are important extracellular allergens released in a short time period- e.g. Amb a 5 in 16 minutes, versus the major allergens described. Amb a 1 and 2, in 12-24 hours. However, these authors and others have not reported significant differences in the first-released allergens from the complete and defatted preparations. In our work, we show a difference in the population of the first-released allergens from complete and defatted pollen. We have identified and characterized an allergen located in the lipid fraction that is discarded during the defatting process. The allergen, which appears to be a major pollen glycoprotein, has a molecular mass of 30 kDa and contains at least one disulfide bond. Amino acid sequencing data indicate that the protein has not been previously described from pollen or other sources. Finally, after performing IgE-immunoblots with 25 sera of ragweed-sensitive patients, we have found that the 30 kDa protein is recognized by all of them, thus qualifying it as a major allergen that is perhaps missed in current screens. Furthermore, our results are reinforced by the fact that dogs sensitized to ragweed also uniformly recognize the allergen. These findings suggest that the lipid fraction containing the 30 kDa allergen and possibly others should be included in allergy testing and immunotherapy regimes.

**1039** Seasonal Variation in the Indoor Mold Aerospora Among Inner-city Homes

H James Wedner, Anupma Dixit, Roosevelt Peabody Washington University School of Medicine, St Louis, MO

**INTRODUCTION:** Sensitization to the indoor mold aerospora may play a significant role in the increasing prevalence of asthma among inner-city dwelling children and adults. To evaluate indoor mold contamination, we have used volumetric spore sampling for both total and viable spores in 40 homes in the East St. Louis, IL (ESL) area.

**METHODS:** At least one asthmatic patient (usually 2 or more) resided in each of the homes selected. Sampling was carried out throughout the year using a Burkard Personal Volumetric spore trap and viable spore trap. Viable spores were collected onto MEA plates. The kitchen, TV room and
